Chap 5. Pointers and Memory management

- Week 8&9

- Eng. Sylvain Manirakiza -

Sun - March 23, 2025

Quick recap of Chap 4

- ❑ Modular programming helps structure and organize code.
- ❑ **Predefined functions** save time and improve efficiency.
- ❑ **User-defined functions** allow reusability.
- ❑ **Recursion** is useful for solving complex problems using smaller steps.

+ 2 For a quick show of

- ❑ **Recursion** is useful for solving complex problems using smaller steps.

Exercices - Modular pseudocode

1. Write a Function to Calculate the Area of a Rectangle and displays the result.
2. Write a function **is_even(n)** that checks if a number is even. The main program should take input from the user and call the function.
3. Write a modular pseudocode program that converts Celsius to Fahrenheit using a function.
4. Write a recursive function that calculates the factorial of a number.
5. Write a function that takes three numbers and returns the largest.

Exercices #1 - Responses

Function **calculate_area**(length, width)

$area \leftarrow length * width$

 Return area

End Function

Start

 Write "Enter length: "

 Read length

 Write "Enter width: "

 Read width

$result \leftarrow calculate_area(length, width)$

 Write "The area of the rectangle is: ", result

End

Exercices #2 - Responses

Function **is_even(n)**

 If $n \text{ MOD } 2 = 0$ Then

 Return "Even"

 Else

 Return "Odd"

 End If

End Function

Start

 Write "Enter a number: "

 Read num

$result \leftarrow is_even(num)$

 Write "The number is: ", result

End

Exercices #3 - Responses

Function **celsius_to_fahrenheit(celsius)**

$fahrenheit \leftarrow (celsius * 9/5) + 32$

Return fahrenheit

End Function

Start

Write "Enter temperature in Celsius: "

Read tempC

$tempF \leftarrow celsius_to_fahrenheit(tempC)$

Write "Temperature in Fahrenheit: ", tempF

End

Exercices #4 - Responses

*Function **factorial**(n)*

If $n = 1$ Then

Return 1

Else

*Return $n * \text{factorial}(n - 1)$*

End If

End Function

Start

Write "Enter a number: "

Read num

result \leftarrow factorial(num)

Write "Factorial of ", num, " is: ", result

End

Exercices #5 - Responses

```
Function find_max(a, b, c)
  If a >= b AND a >= c Then
    Return a
  Else If b >= a AND b >= c Then
    Return b
  Else
    Return c
  End If
End Function
```

```
Start
  Write "Enter first number: "
  Read num1
  Write "Enter second number: "
  Read num2
  Write "Enter third number: "
  Read num3

  max_value ← find_max(num1, num2,
num3)
  Write "The largest number is: ",
max_value
End
```

Chap 5: Pointers and Memory Management

```
// ( types, selector, data )
if ( typeof selector == "string" ) {
    // ( types-Object, data )
    data = data || selector;
    selector = undefined;
}
for ( type in types ) {
    on( elem, type, selector, data, types[ type ]. use );
}
return elem;
}

if ( data == null && fn == null ) {
    // ( types, fn )
    fn = selector;
    data = selector = undefined;
} else if ( fn == null ) {
    if ( typeof selector == "string" ) {
        // ( types, selector, fn )
        fn = data;
        data = undefined;
    } else {
        // ( types, data, fn )
        fn = data;
        data = selector;
        selector = undefined;
    }
}
```

What is a Pointer?

A blurred image showing several lines of code in a dark-themed editor. The code appears to be JavaScript or a similar language, featuring comments like '// (types-Object, selector, data)' and various assignments and conditional statements. The text is out of focus, serving as a background for the slide.

```
// ( types-Object, selector, data )
if ( typeof selector === "string" ) {
  // ( types-Object, data )
  data = data || selector;
  selector = undefined;
}
for ( type in types ) {
  on( elem, type, selector, data, types[ type ], use );
}
return elem;
}

if ( data == null && fn == null ) {
  // ( types, fn )
  fn = selector;
  data = selector = undefined;
} else if ( fn == null ) {
  if ( typeof selector === "string" ) {
    // ( types, selector, fn )
    fn = data;
    data = undefined;
  } else {
    // ( types, data, fn )
    fn = data;
    data = selector;
    selector = undefined;
  }
}
```

- A pointer is a variable that stores the memory address of another variable. Unlike **normal variables** it does not store user given or processed value, instead **it stores valid computer memory address**.
- Think of it as a "**reference**" to a location in memory.

Why Use Pointers?

- Direct memory access for efficiency.
- Dynamic memory allocation.
- Enables complex data structures like linked lists, trees, and graphs.

```
// ( types, selector, data )
if ( typeof selector == "string" ) {
  // ( types, data )
  data = data || selector;
  selector = undefined;
}
for ( type in types ) {
  on( elem, type, selector, data, types[ type ], on );
}
return elem;
}

if ( data == null && fn == null ) {
  // ( types, fn )
  fn = selector;
  data = selector = undefined;
} else if ( fn == null ) {
  if ( typeof selector == "string" ) {
    // ( types, selector, fn )
    fn = data;
    data = undefined;
  } else {
    // ( types, data, fn )
    fn = data;
    data = selector;
    selector = undefined;
  }
}
```

Memory Basics

- **Memory Addresses**

- Every variable is stored in memory at a unique address.
- *Example: `int X = 5;` → `x` is stored at address `1000`.*

Memory Basics

● Visualization

Memory		
Address	Variable	Value
1000	X	5
1004	Y	10
1008	Z	15

In this diagram:

- **x** is stored at address 1000 with a value of 5.
- **y** is stored at address 1004 with a value of 10.
- **z** is stored at address 1008 with a value of 15.

Pointers in Memory

Memory		
Address	Variable	Value
1000	X	5
1004	Y	10
1008	Z	15

Pointers

← ptr_x

← ptr_y

← ptr_z

Pointers in Memory

Memory

Address	Variable	Value
1000	X	5
1004	Y	10
1008	Z	15
1012	ptr_x	1000
1016	ptr_y	1004
1020	ptr_z	1008

Pointers in Memory

- `ptr_x` is a pointer that points to the address **1000**, where the variable `x` is stored.
- `ptr_y` is a pointer that points to the address **1004**, where the variable `y` is stored.
- `ptr_z` is a pointer that points to the address **1008**, where the variable `z` is stored.

Declaring and Using Pointers

- **Assigning Addresses / Referencing**
 - Use the **&** operator to get the address of a variable.
 - *Example: SET ptr TO &X or p ←&X*
- **Dereferencing Pointers**
 - Use the ***** operator to access the value at the address.
 - *Example: PRINT "Value at address stored in ptr: ", or*
 - *Write *ptr*

Declaration and Using Pointers

- You can access a variable in two ways.
 - **Direct Access:** *You can directly use the variable name to access the variable.*
 - **Indirect Access:** *You use a pointer to access that variable.*

```
declare int a, *ptr;      //declaration
ptr=&a;                    //initialization
write ("direct access("Direct Access, a=a);
write("Indirect Access, a=*ptr);
```

Pseudocode Example

- *Variable $y \leftarrow 10$*
- *Pointer $\text{ptr_y} \leftarrow \&y$ // store address of y in ptr*
- *Write "Address stored in ptr_y : ", ptr_y*
- *Write "Value pointed by ptr_y : ", $*\text{ptr_y}$*

Output:

Address stored in ptr_y : 1004

Value pointed by ptr_y : 10

Pointer Example in Pseudo-code

- *DECLARE X AS INTEGER*
- *DECLARE ptr AS POINTER TO INTEGER*
- *SET X TO 42*
- *SET ptr TO &X*
- *PRINT "Value of X: ", X*
- *PRINT "Address of X: ", &X*
- *PRINT "Value at address stored in ptr: ", *ptr*

Dynamic Memory Allocation

- **What is Dynamic Memory Allocation?**
 - Allocating memory at **runtime** instead of **compile time**.
 - Useful when the size of data is unknown beforehand.

Dynamic Memory Allocation

- Pseudo-code for Allocation
 - Use **ALLOCATE** and **DEALLOCATE** keywords.
 - *Example:*

Dynamic Memory Allocation - Example

DECLARE ptr AS POINTER TO INTEGER

ALLOCATE ptr

*SET *ptr TO 100*

*PRINT "Value at allocated memory: ", *ptr*

DEALLOCATE ptr

Memory Management

- **Why Manage Memory?**
 - Prevent memory leaks (unused memory not deallocated).
 - Avoid dangling pointers (pointers to deallocated memory).
- **Best Practices**
 - Always deallocate memory after use.
 - Set pointers to NULL after deallocation.

Common Pointer Errors

- **Null Pointers**

- Pointers that do not point to any valid memory location.

- **Dangling Pointers**

- Pointers that reference deallocated memory.

- **Memory Leaks**

- Forgetting to deallocate memory.

Example of Memory Leak in Pseudo-code

DECLARE ptr AS POINTER TO INTEGER

ALLOCATE ptr

*SET *ptr TO 50*

// Forgot to DEALLOCATE ptr → Memory Leak!

Pointers and Arrays

Arrays as Pointers

- An array name is essentially a pointer to its first element.
- Example:

Example of Memory Leak in Pseudo-code

```
DECLARE arr[3] AS INTEGER  
SET arr[0] TO 10  
SET arr[1] TO 20  
SET arr[2] TO 30  
  
DECLARE ptr AS POINTER TO INTEGER  
SET ptr TO arr  
  
PRINT "First element: ", *ptr  
  
PRINT "Second element: ", *(ptr + 1)
```

Pointers and Functions

Passing Pointers to Functions

- Allows functions to modify the original data
- *Example(Next Slide):*

Pointers and Functions

```
FUNCTION increment(ptr AS POINTER TO INTEGER)
```

```
    SET *ptr TO *ptr + 1
```

```
END FUNCTION
```

```
DECLARE X AS INTEGER
```

```
SET X TO 5
```

```
CALL increment(&X)
```

```
PRINT "Value of X after increment: ", X
```

Recap

1. Pointers store memory addresses.
2. Dynamic memory allocation allows runtime memory management.
3. Proper memory management prevents leaks and errors.
4. Pointers enable powerful programming techniques.

Applications

Write pseudocode to:

1. Dynamically allocate space for 4 numbers
2. Read values into memory using a pointer
3. Calculate and print their total sum
4. Free the memory

Pseudocode Solution

Start

Pointer $p \leftarrow \text{Allocate}(4)$ // Allocate space for 4 numbers

sum $\leftarrow 0$

For $i \leftarrow 0$ to 3 Do

Write "Enter number ", $i+1$, ":"

Read $p[i]$ // Store input at allocated address

sum $\leftarrow \text{sum} + p[i]$

End For

Write "Total sum is: ", sum

Free(p) // Release the allocated memory

End

Exercises

1. Write pseudo-code to swap two numbers using pointers.
2. Write a function that accepts a pointer to an array of 3 integers and returns the sum.

Responses - #1

```
Function swap(aPointer, bPointer)
```

```
    temp ← *aPointer
```

```
    *aPointer ← *bPointer
```

```
    *bPointer ← temp
```

```
End Function
```

```
Start
```

```
    Variable x ← 10
```

```
    Variable y ← 20
```

```
    Pointer px ← &x
```

```
    Pointer py ← &y
```

```
    Write "Before swap: x = ", x, ", y = ", y
```

```
    Call swap(px, py)
```

```
    Write "After swap: x = ", x, ", y = ", y
```

```
End
```

Responses - #2

```
Function sumArray(p)
```

```
    sum ← 0
```

```
    For i ← 0 to 2 Do
```

```
        sum ← sum + p[i]
```

```
    End For
```

```
    Return sum
```

```
End Function
```

```
Start
```

```
    Pointer arr ← Allocate(3)
```

```
    arr[0] ← 3
```

```
    arr[1] ← 5
```

```
    arr[2] ← 7
```

```
    result ← sumArray(arr)
```

```
    Write "Sum is: ", result
```

```
    Free(arr)
```

```
End
```
